# Contents

- The RCS at IPNS
- Observation of the vertical instability
- Cures
- Summary

# The RCS: Rapid Cycling Synchrotron

Intense Pulsed Neutron Source

Circumference	42.95 m
Injection energy	50 MeV
extraction energy	450 MeV
Revolution	2.21-----
frequency	5.14 MHz
tunes	x: 2.21 y: 2.31
Injected pulse length	75 us
Injected charge	3.6e12 H-
Repeat rate	30 Hz
Overall efficiency	88%

## The operation of RCS

- In the early '80s, a **head-tail instability** was found. It was cured with the addition of sextupoles.

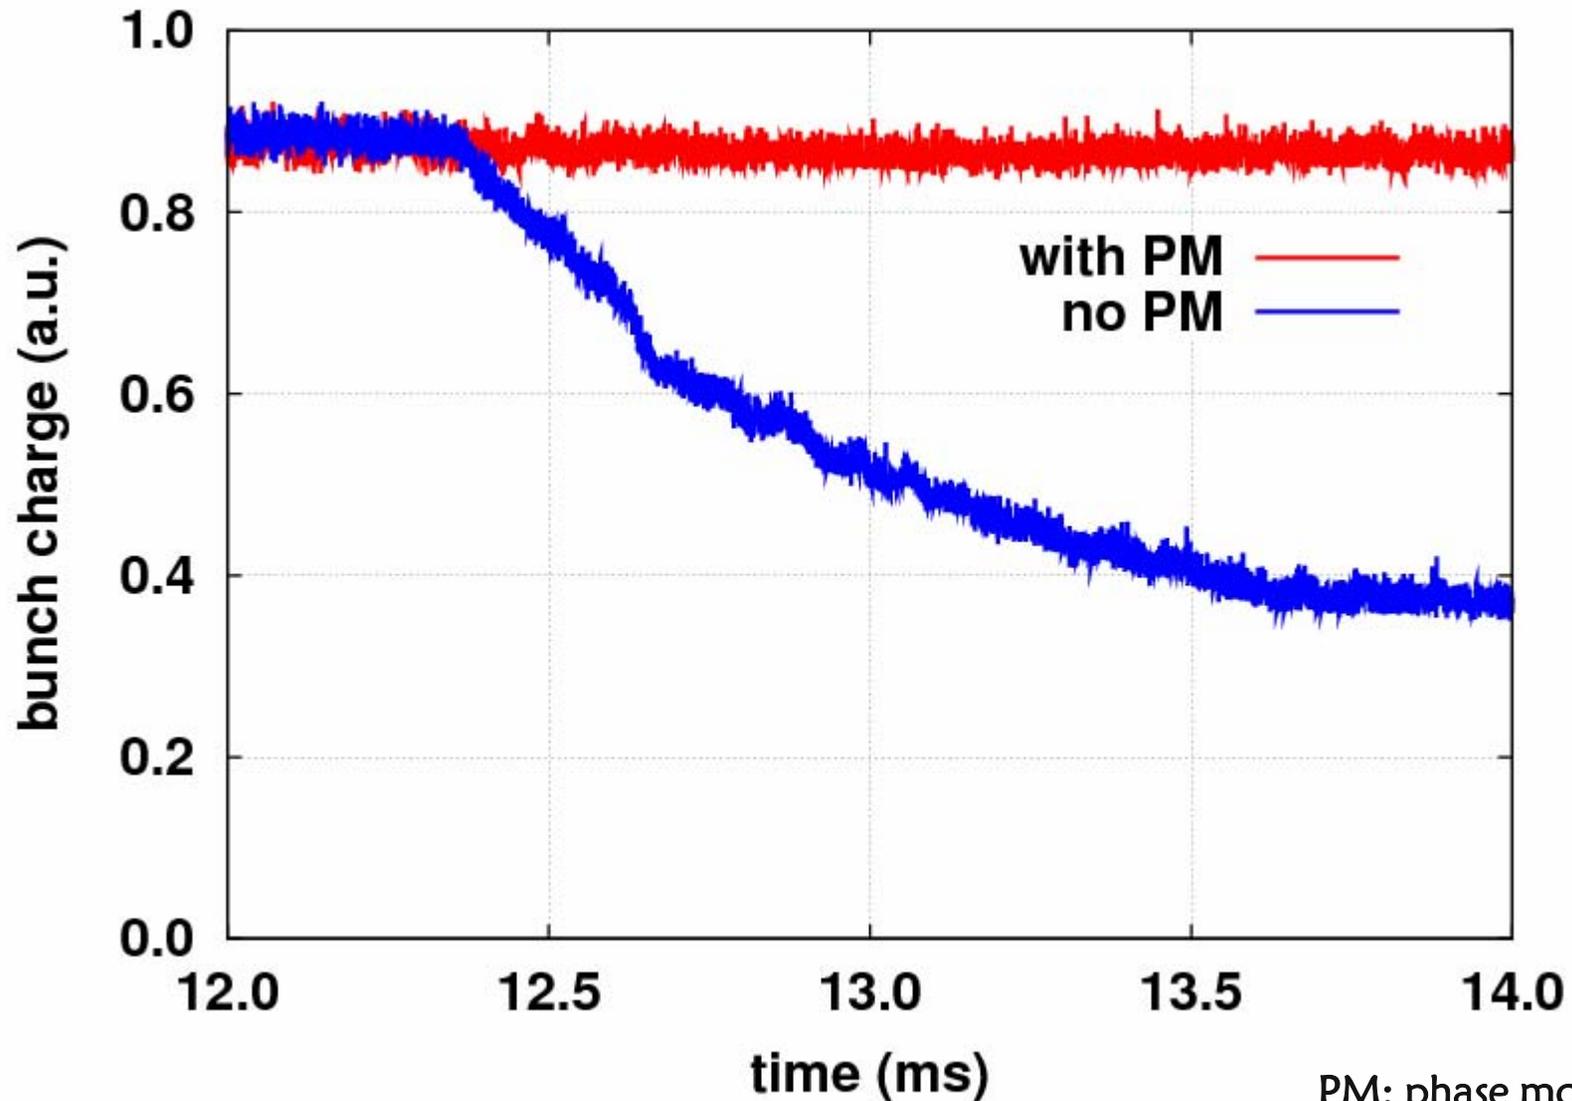

$I_{\text{Ave}}$ : 5  $\mu\text{A}$   $\rightarrow$  11  $\mu\text{A}$

- The next threshold appeared to be from a **vertical instability**. The cure was RF cavity phase modulation (PM) later in the cycle.

$I_{\text{Ave}}$ : 11  $\mu\text{A}$   $\rightarrow$  15  $\mu\text{A}$

# Observation of beam loss with Resistive Wall Monitor

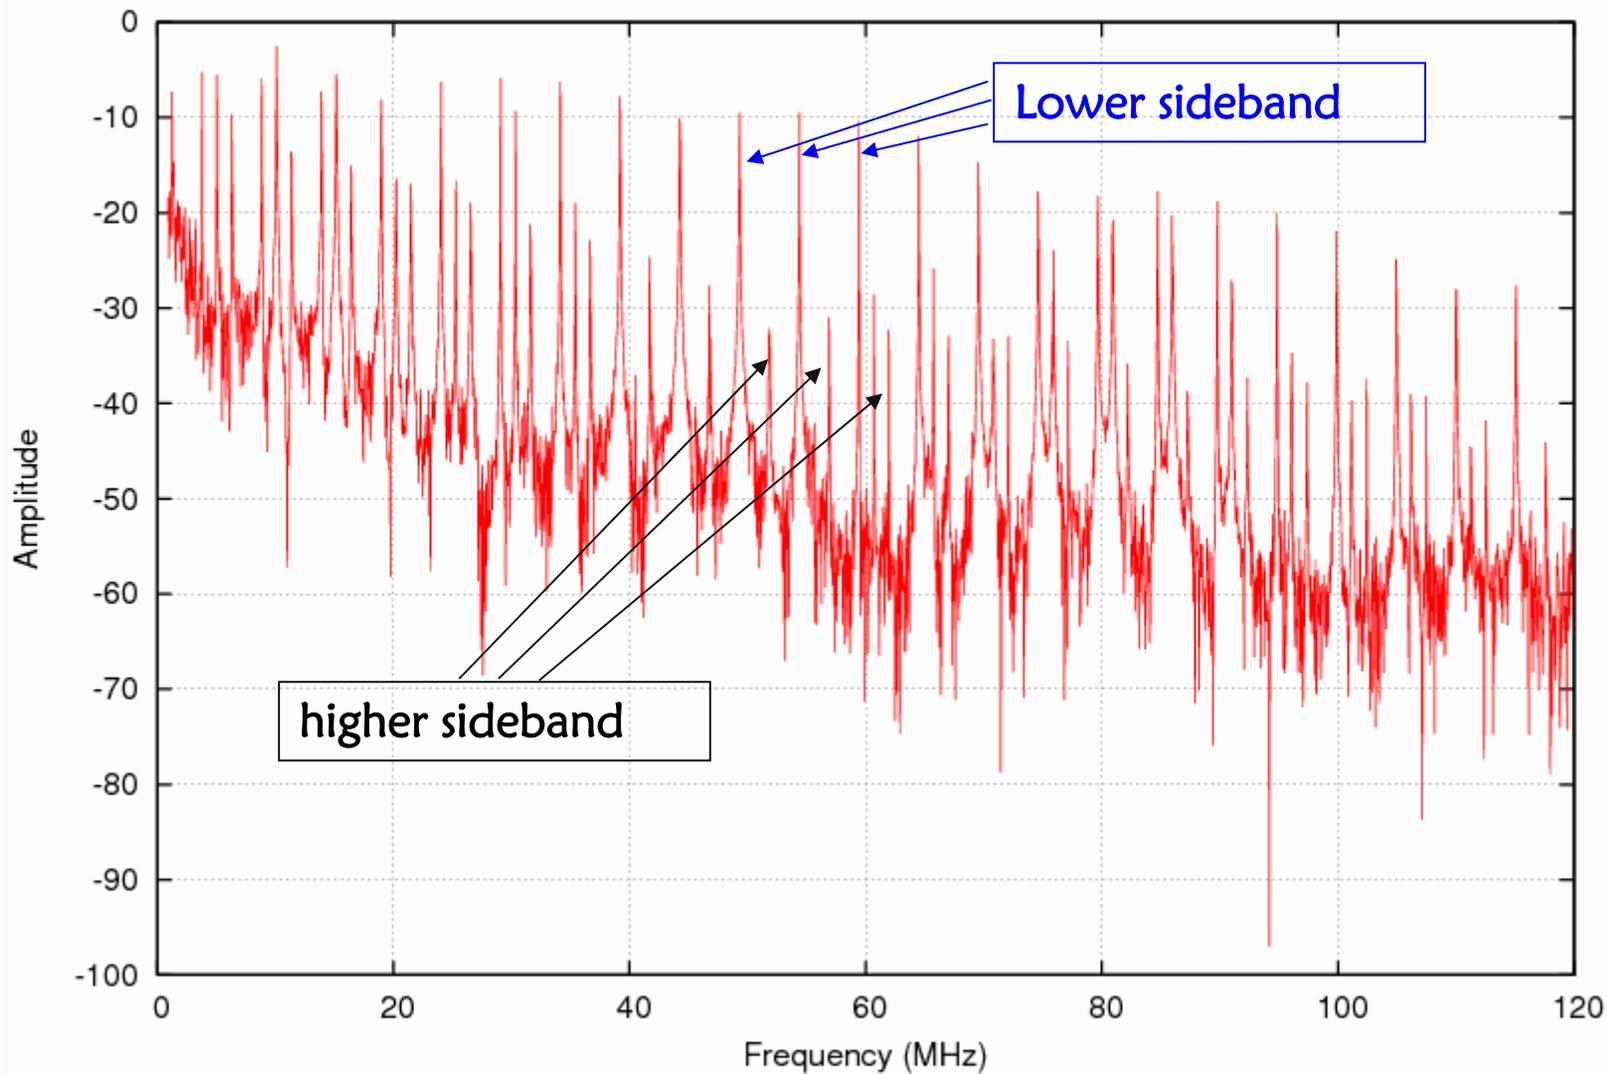

## Bunch charge

PM: phase modulation

# Spectrum with instability

vf\_ns\_2\_500mV: (CH4-CH3) FFT results of 13.88 to 13.90 ms

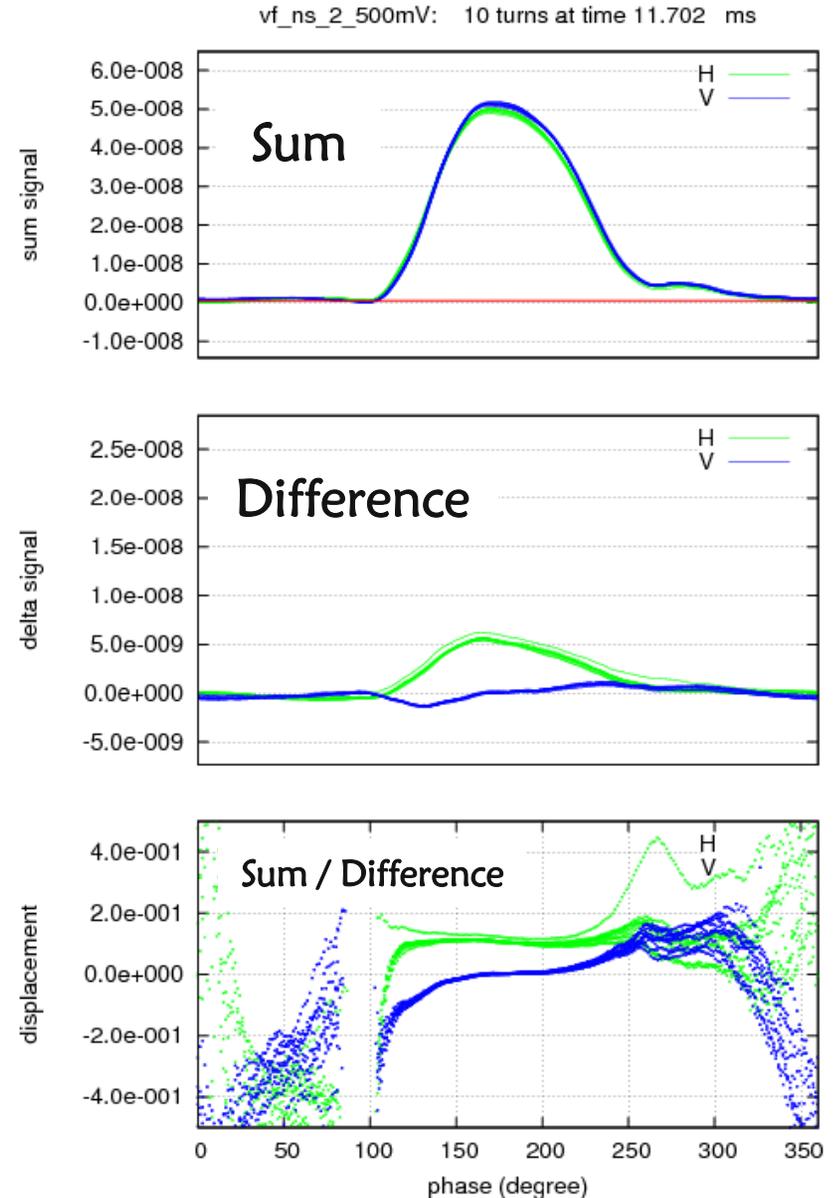

# Conversion of beam position monitor signals

The revolution period shrinks as the bunch's energy steps up.

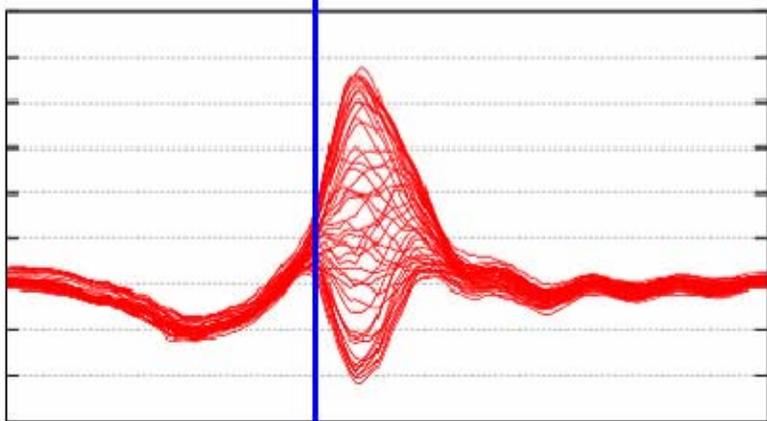

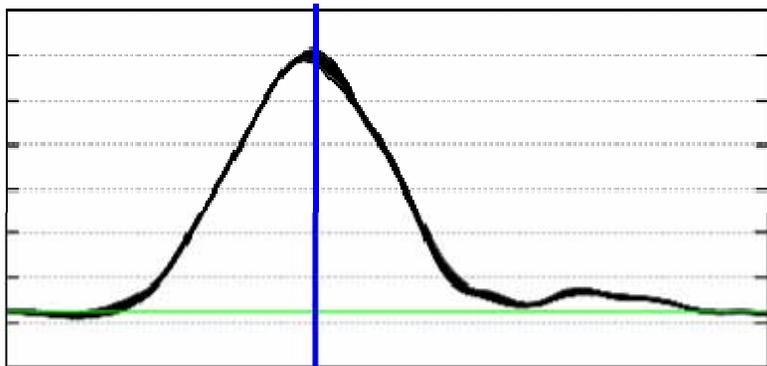

In order to view the centroid motion on a turn-by-turn basis,

- BPM signals are separated into single turns,
- then for each single turn, BPM signals are converted into rf phase basis,
- then single turn BPM signals can be overlaped.

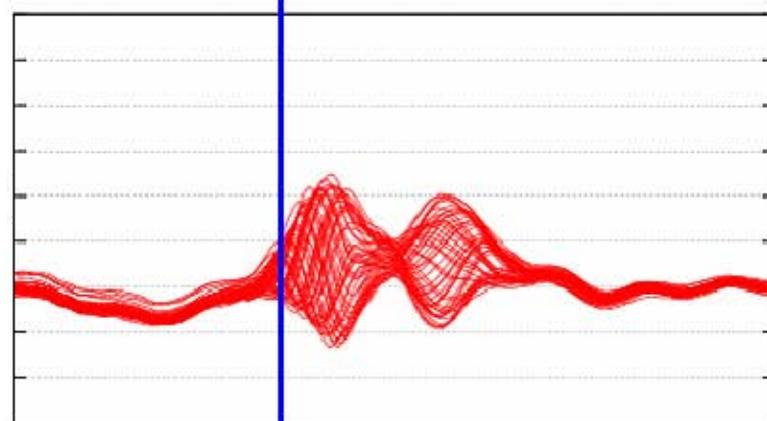

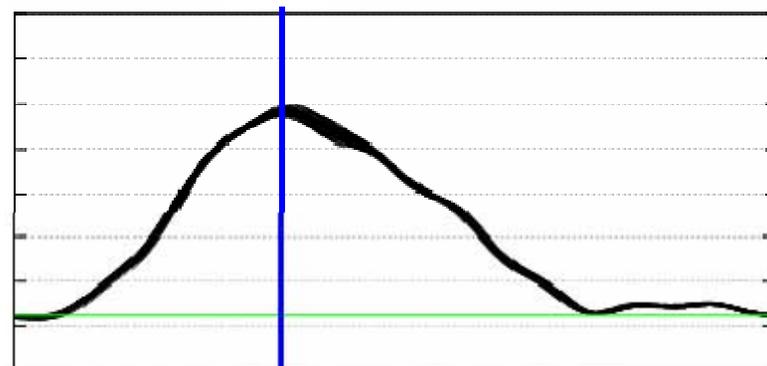

# *In the vertical plane, instabilities in tail only, 2 modes*

## Mode 0

## Mode 1

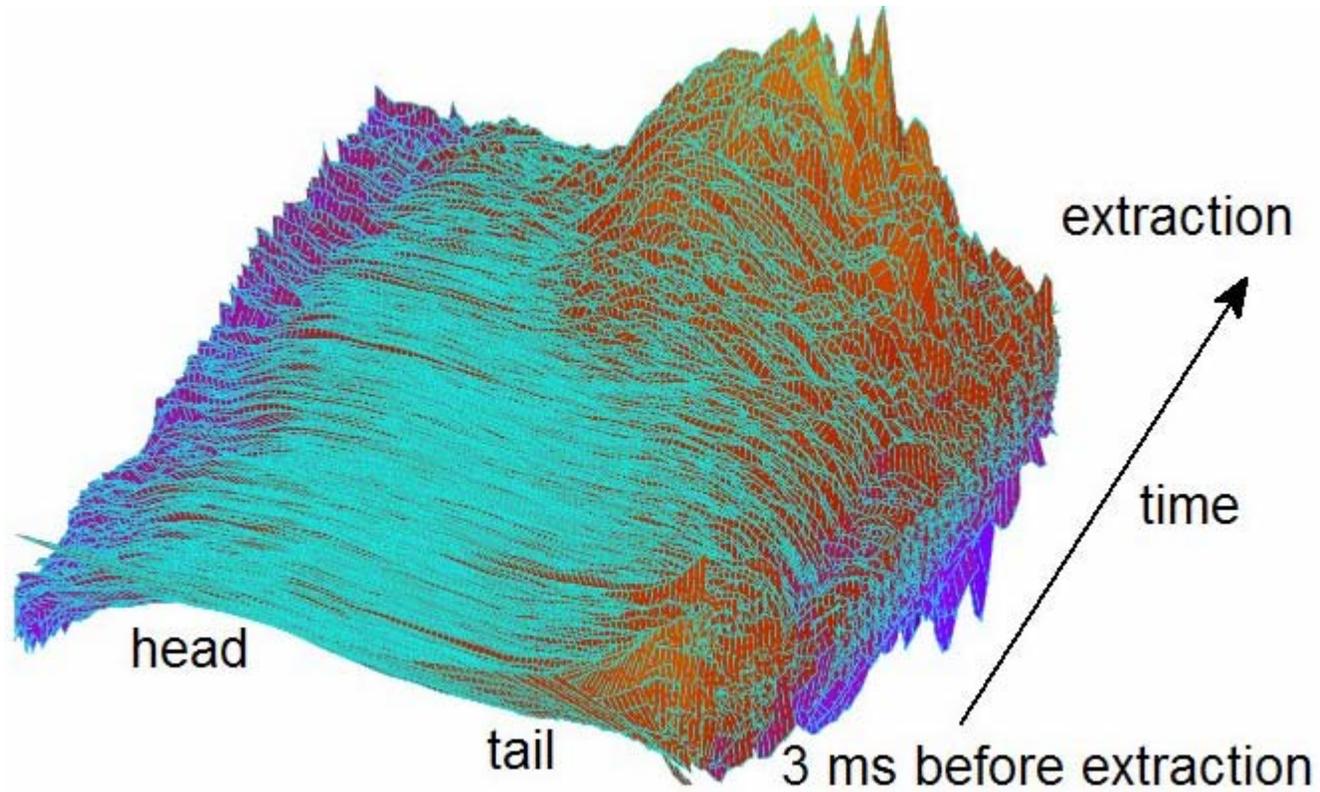

Sum

Difference

50 turns BPM signals are shown

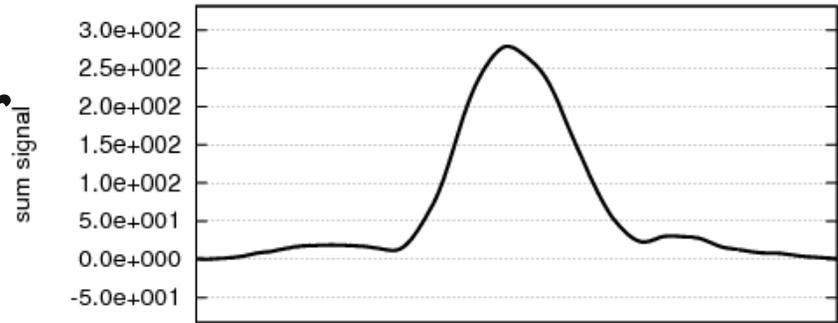

# *The oscillation starts from the tail*

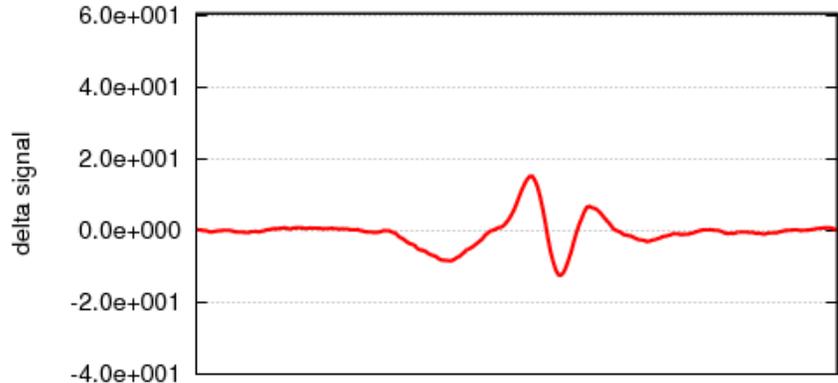

# Vertical Centroid Oscillation in the Tail

vf\_ns\_2\_500mV(V): 1 turns at time 14.3664 ms

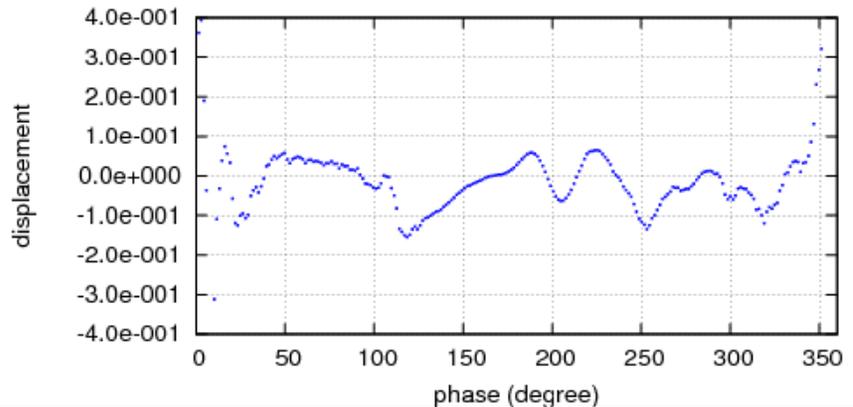

## Beam Position Monitor (BPM) sum signal

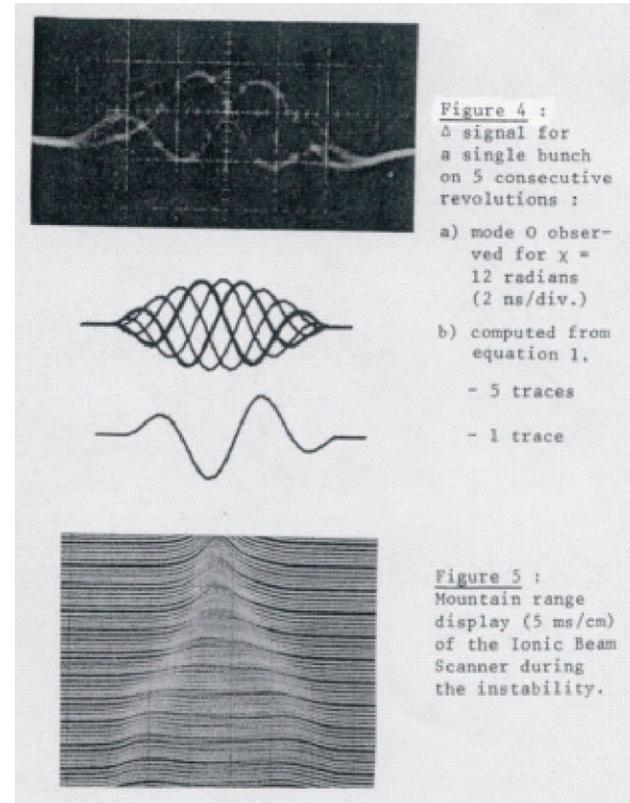

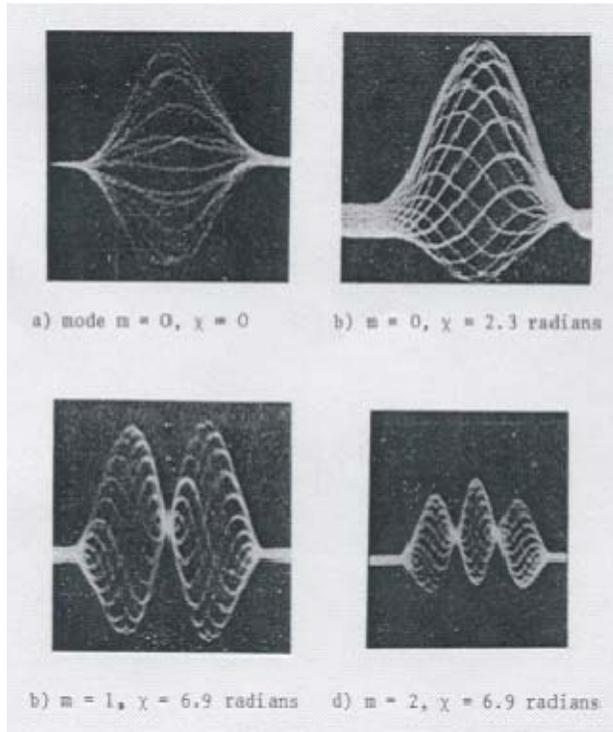

## BPM difference signal

## Sum/difference

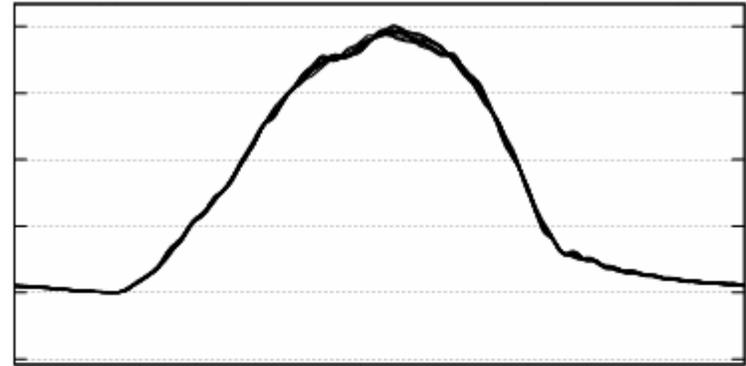

## Classical head-tail

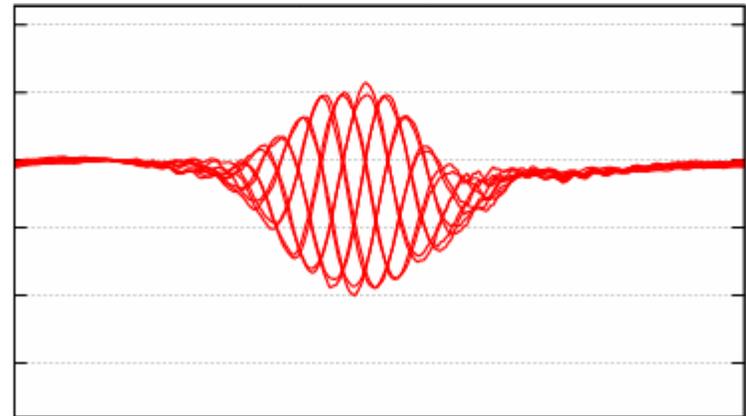

# *We turned off the sextupole to induce a head-tail at RCS*

BPM sum signal

BPM difference signal

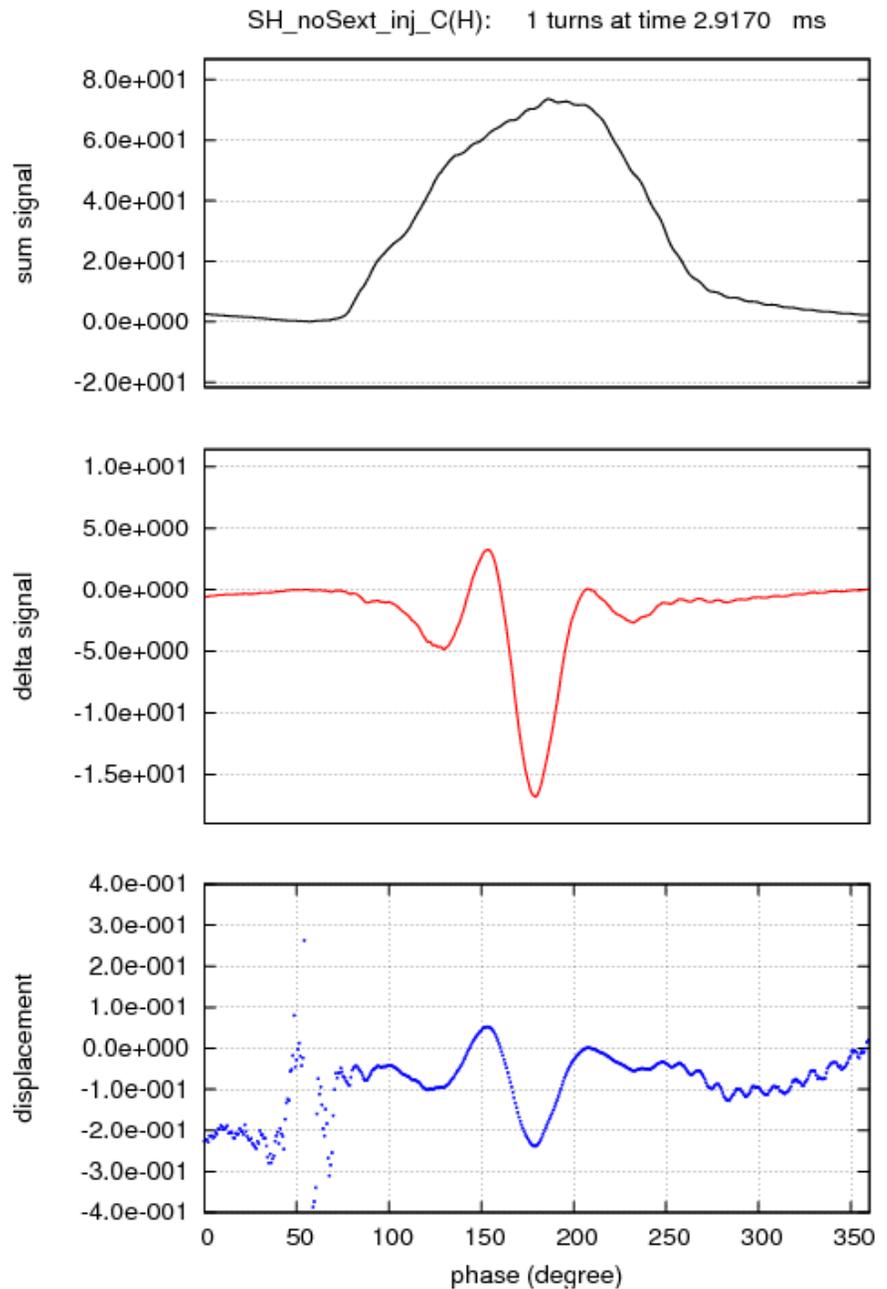

# Classical head-tail at RCS

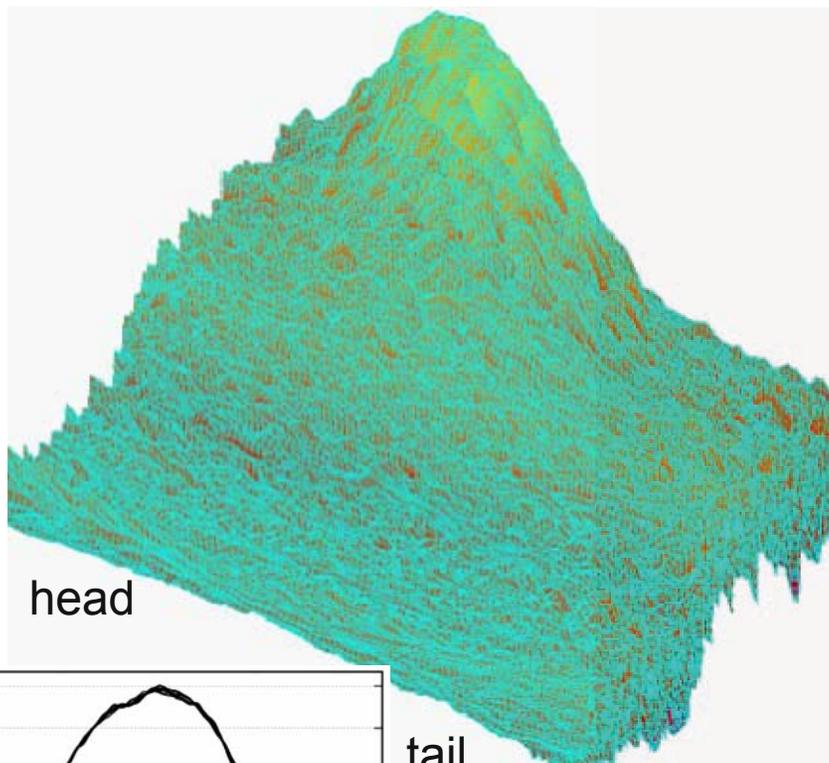

BPM sum signal

BPM difference signal

Sum/difference

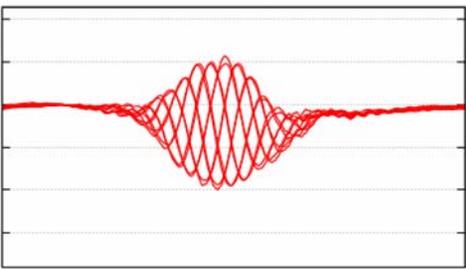

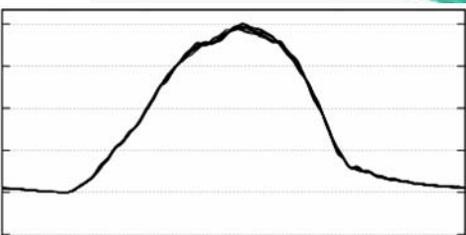

# No sextupole, classical head-tail

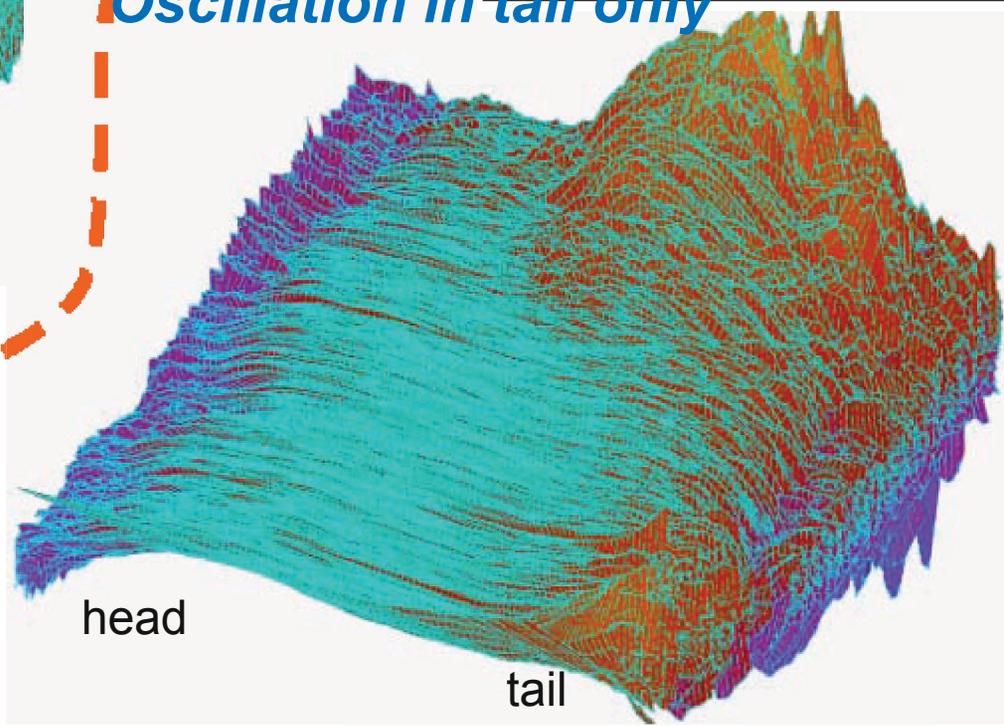

head

tail

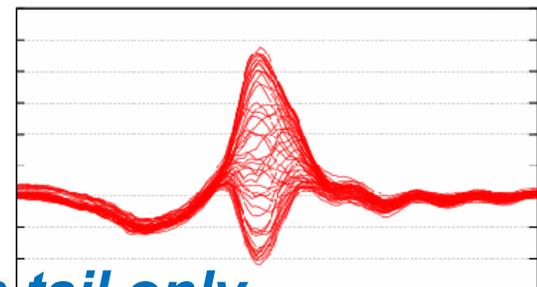

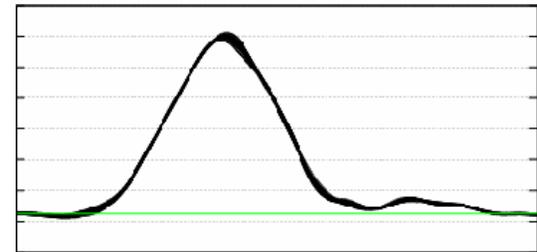

Oscillation in tail only

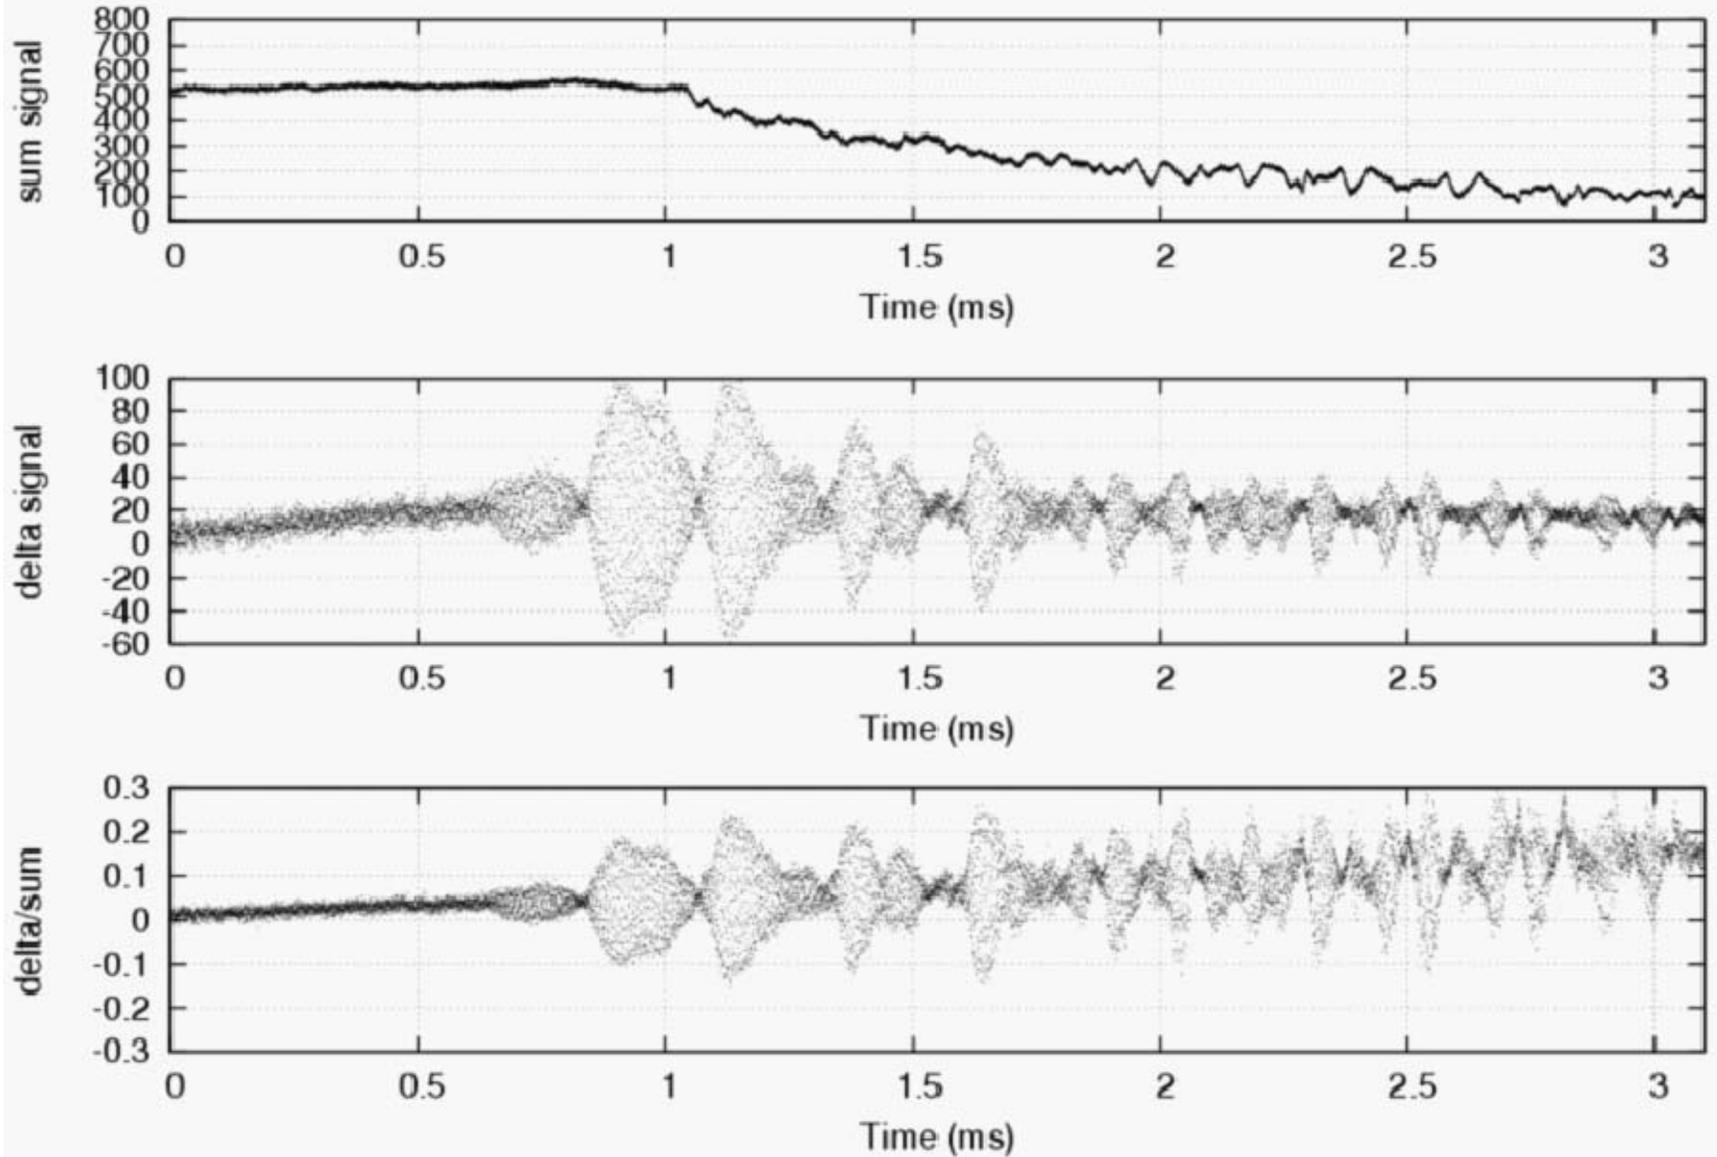

head

tail

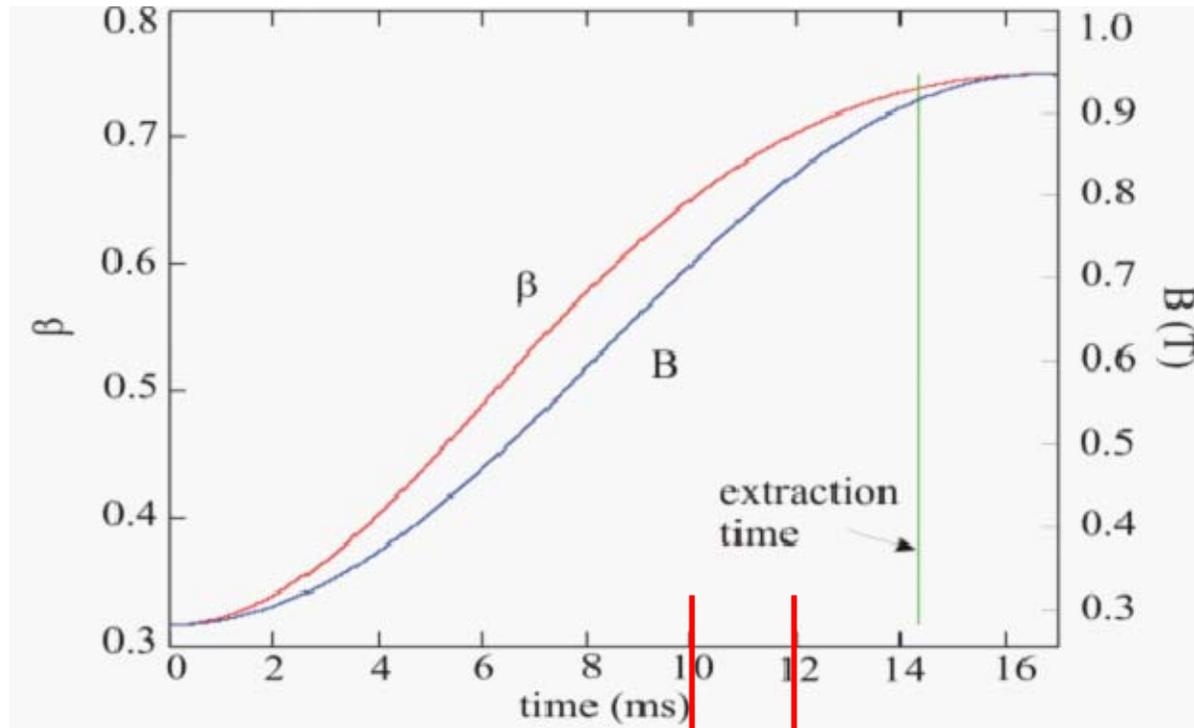

# Tail oscillation starts before beam loss

350inj\_11p7\_13p9\_3\_ns: (CH34), Slice 21 at 212 degree, Show\_Ave

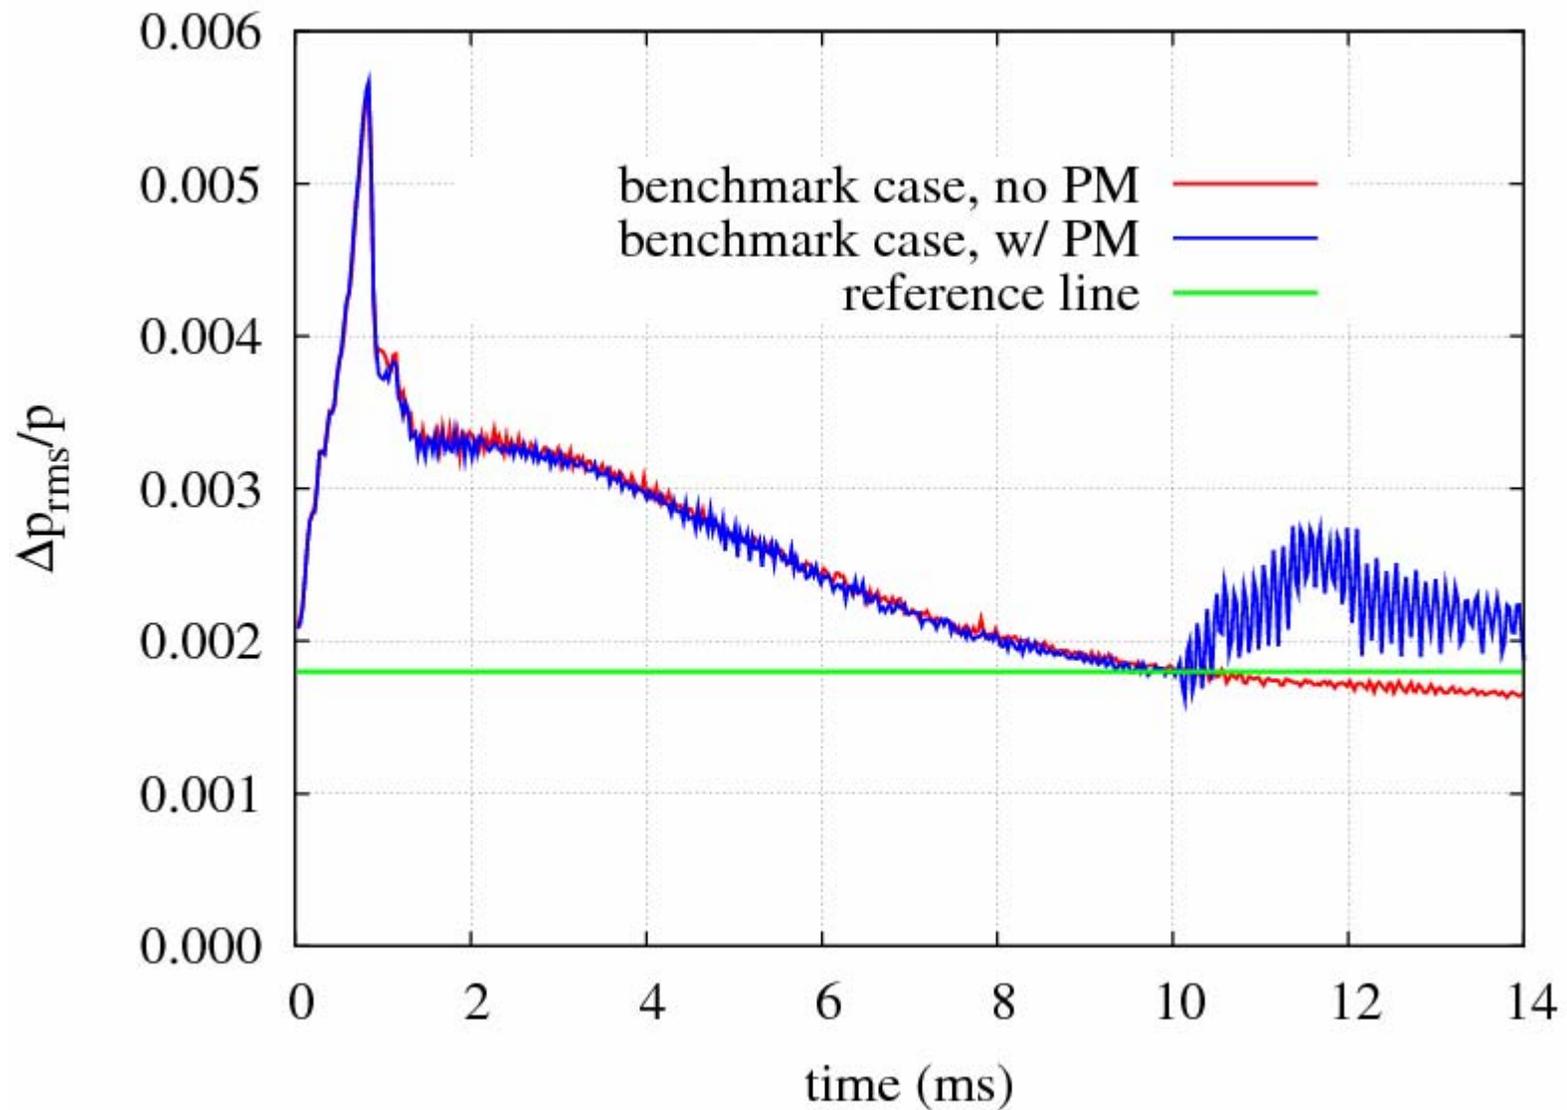

# Phase Modulation (PM) at $2f_s$ in the RCS

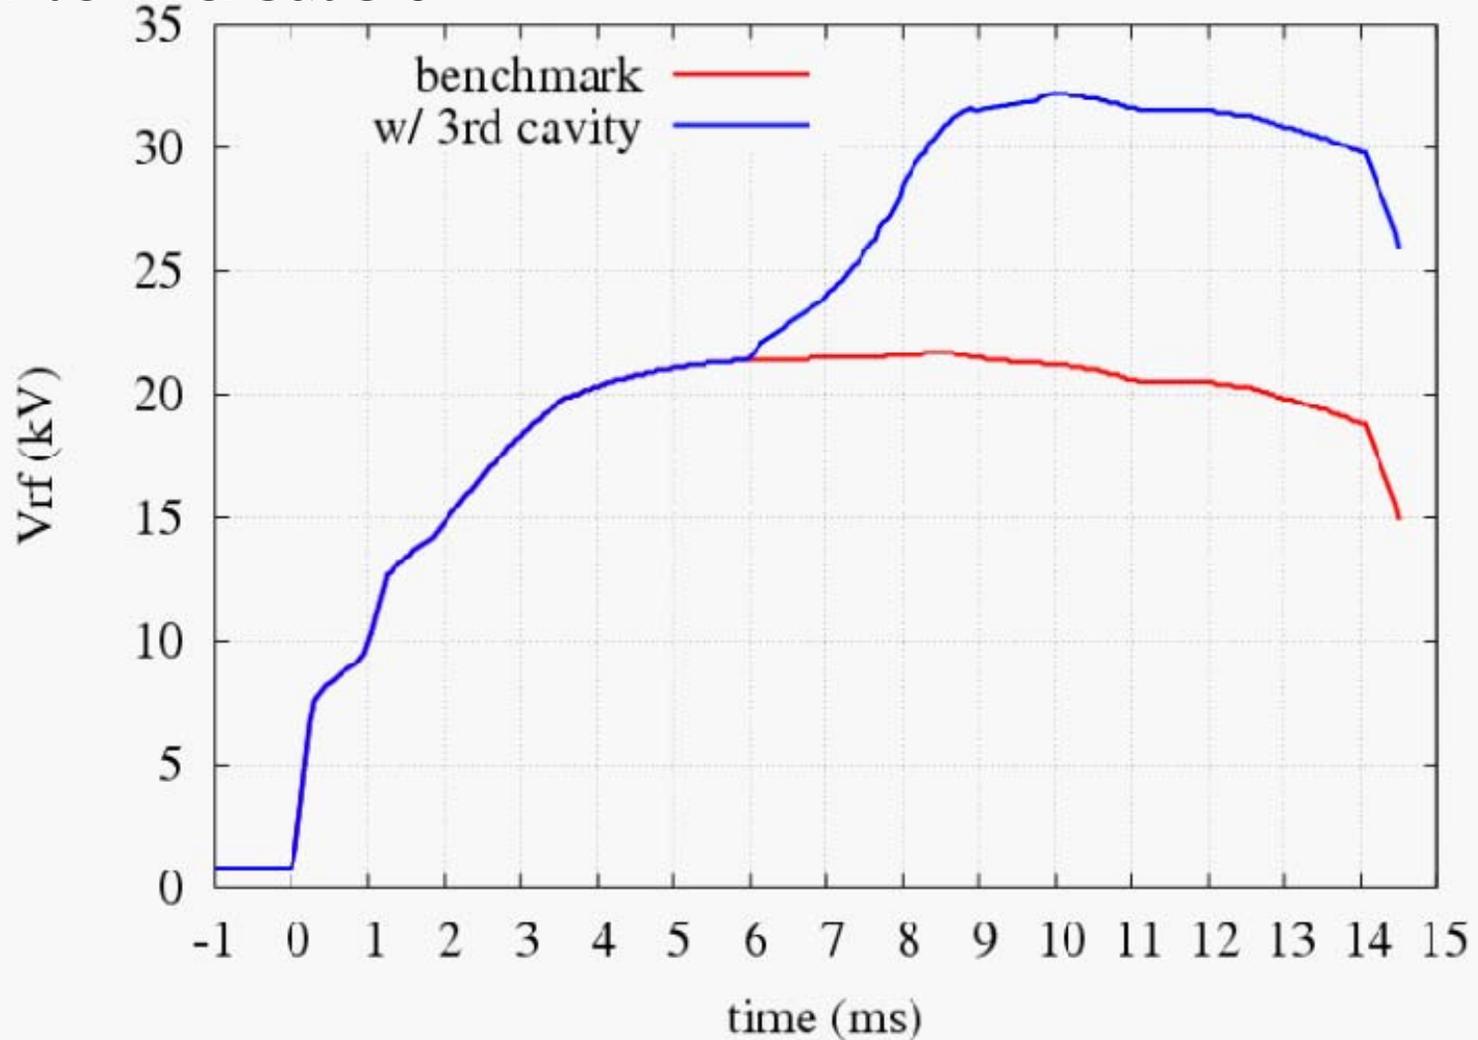

PM frequency 10 kHz,  
PM amplitude 4.3 degree

# Simulation, PM increase $\Delta p/p$

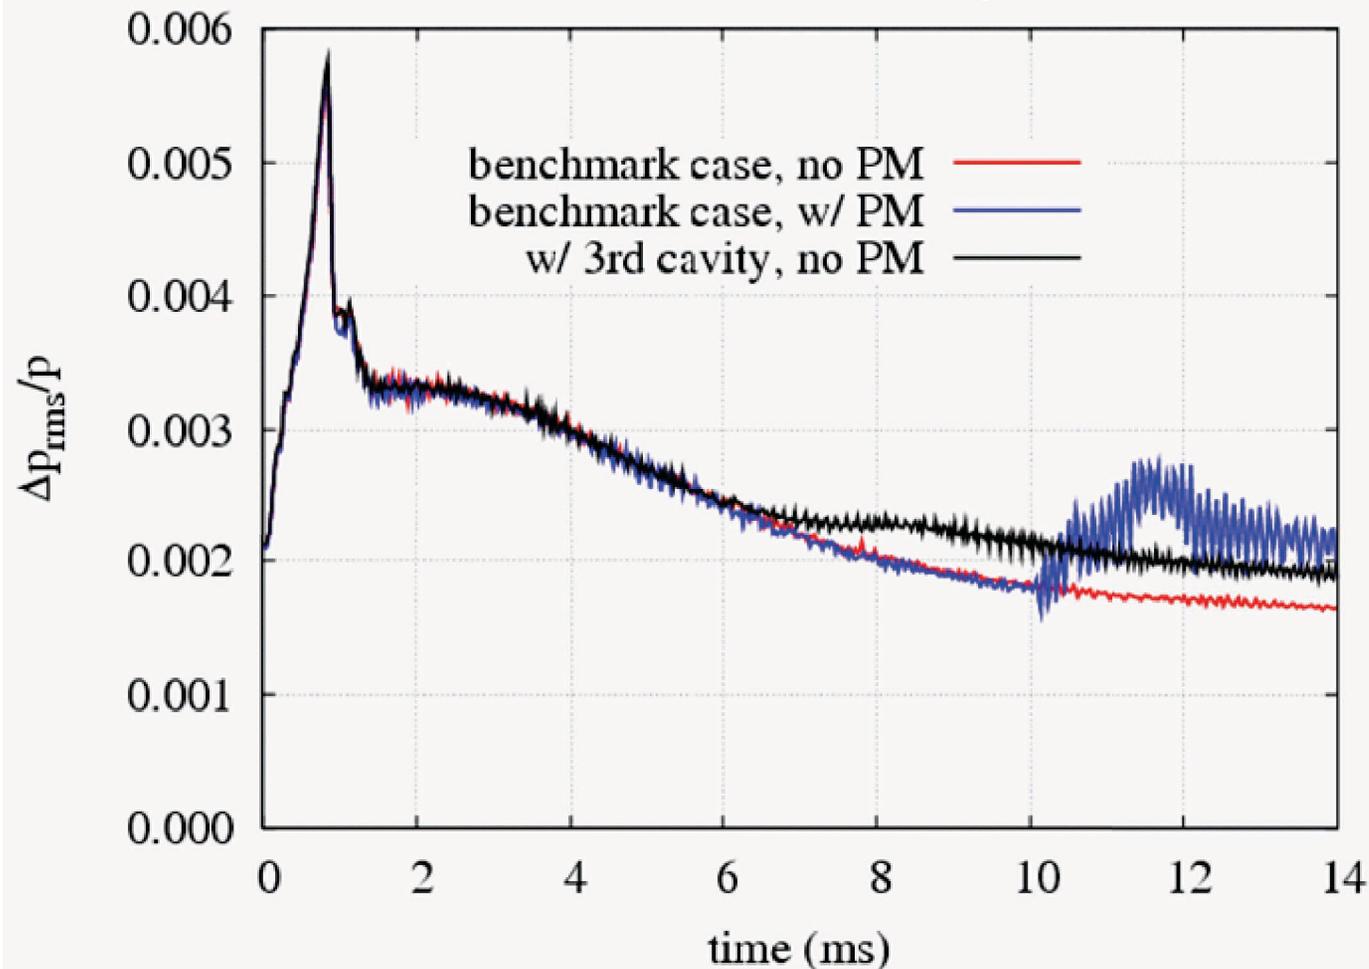

## Utilize the 3rd cavity

We can utilize the 3<sup>rd</sup> cavity to increase the total  $V_{rf}$  to increase  $\delta$

## Simulation, higher Vrf increase $\Delta p/p$

We can see that the increase of Vrf in the later cycle improves  $\delta$  correspondingly

## Summary:

- The vertical instability is limited in the tail
- The characteristics of classical HT instability is different from our observation
- Investigating to use 3rd cavity to increase threshold
- Investigating electron cloud effects in RCS

*The end*

Thank you
